Minimizing large finite sums

Consider the minimization of a large sum of convex functions

$$\min_{x \in \mathbb{R}^d} \left\{ f(x) \stackrel{\triangle}{=} \frac{1}{n} \sum_{i=1}^n f_i(x) + \psi(x) \right\},\,$$

where each f_i is **smooth and convex** and ψ is a convex regularization penalty but not necessarily differentiable.

Motivation

Our goal is to

- accelerate first-order methods with Quasi-Newton heuristics;
- design algorithms that can adapt to composite and finite-sum structures and that can also exploit curvature information.

[Byrd et al., 2016, Gower et al., 2016]

QuickeNing: main idea

Idea: Smooth the function and then apply Quasi-Newton.

 The strategy appears in early work about variable metric bundle methods. [Chen and Fukushima, 1999, Fukushima and Qi, 1996, Mifflin, 1996, Fuentes, Malick, and Lemaréchal, 2012, Burke and Qian, 2000] ...

QuickeNing: main idea

Idea: Smooth the function and then apply Quasi-Newton.

 The strategy appears in early work about variable metric bundle methods. [Chen and Fukushima, 1999, Fukushima and Qi, 1996, Mifflin, 1996, Fuentes, Malick, and Lemaréchal, 2012, Burke and Qian, 2000] ...

The Moreau-Yosida smoothing

Given $f: \mathbb{R}^d \to \mathbb{R}$ a convex function, the Moreau-Yosida smoothing of f is the function $F: \mathbb{R}^d \to \mathbb{R}$ defined as

$$F(x) = \min_{w \in \mathbb{R}^d} \left\{ f(w) + \frac{\kappa}{2} ||w - x||^2 \right\}.$$

The **proximal operator** p(x) is the unique minimizer of the problem.

The Moreau-Yosida regularization

$$F(x) = \min_{w \in \mathbb{R}^d} \left\{ f(w) + \frac{\kappa}{2} ||w - x||^2 \right\}.$$

Basic properties [see Lemaréchal and Sagastizábal, 1997]

• Minimizing f and F is equivalent in the sense that

$$\min_{x \in \mathbb{R}^d} F(x) = \min_{x \in \mathbb{R}^d} f(x),$$

and the solution set of the two problems coincide with each other.

• F is continuously differentiable even when f is not and

$$\nabla F(x) = \kappa(x - p(x)).$$

In addition, ∇F is Lipschitz continuous with parameter $L_F = \kappa$.

• If f is μ -strongly convex then F is also strongly convex with parameter $\mu_F = \frac{\mu\kappa}{\mu + \kappa}$.

Julien Mairal

The Moreau-Yosida regularization

$$F(x) = \min_{w \in \mathbb{R}^d} \left\{ f(w) + \frac{\kappa}{2} ||w - x||^2 \right\}.$$

Basic properties [see Lemaréchal and Sagastizábal, 1997]

Minimizing f and F is equivalent in the sense that

$$\min_{x \in \mathbb{R}^d} F(x) = \min_{x \in \mathbb{R}^d} f(x),$$

and the solution set of the two problems coincide with each other.

ullet F is continuously differentiable even when f is not and

$$\nabla F(x) = \kappa(x - p(x)).$$

In addition, ∇F is Lipschitz continuous with parameter $L_F = \kappa$.

F enjoys nice properties: smoothness, (strong) convexity and we can control its condition number $1+\kappa/\mu$.

Julien Mairal

QuickeNing

A fresh look at Catalyst

A fresh look at the proximal point algorithm

A naive approach consists of minimizing the smoothed objective F instead of f with a method designed for smooth optimization.

Consider indeed

$$x_{k+1} = x_k - \frac{1}{\kappa} \nabla F(x_k).$$

By rewriting the gradient $\nabla F(x_k)$ as $\kappa(x_k - p(x_k))$, we obtain

$$x_{k+1} = p(x_k) = \arg\min_{w \in \mathbb{R}^p} \left\{ f(w) + \frac{\kappa}{2} ||w - x_k||^2 \right\}.$$

This is exactly the proximal point algorithm [Rockafellar, 1976].

A fresh look at the accelerated proximal point algorithm

Consider now

$$x_{k+1} = y_k - \frac{1}{\kappa} \nabla F(y_k)$$
 and $y_{k+1} = x_{k+1} + \beta_{k+1} (x_{k+1} - x_k),$

where β_{k+1} is a Nesterov-like extrapolation parameter. We may now rewrite the update using the value of ∇F , which gives:

$$x_{k+1} = p(y_k)$$
 and $y_{k+1} = x_{k+1} + \beta_{k+1}(x_{k+1} - x_k)$

This is the accelerated proximal point algorithm of Güler [1992].

A fresh look at the accelerated proximal point algorithm

Consider now

$$x_{k+1} = y_k - \frac{1}{\kappa} \nabla F(y_k)$$
 and $y_{k+1} = x_{k+1} + \beta_{k+1} (x_{k+1} - x_k),$

where β_{k+1} is a Nesterov-like extrapolation parameter. We may now rewrite the update using the value of ∇F , which gives:

$$x_{k+1} = p(y_k)$$
 and $y_{k+1} = x_{k+1} + \beta_{k+1}(x_{k+1} - x_k)$

This is the accelerated proximal point algorithm of Güler [1992].

Remarks

- F may be better conditioned than f when $1 + \kappa/\mu \le L/\mu$;
- Computing $p(y_k)$ has a cost!

A fresh look at Catalyst [Lin, Mairal, and Harchaoui, 2015]

Catalyst is a particular accelerated proximal point algorithm with inexact gradients [Güler, 1992].

$$x_{k+1} \approx p(y_k)$$
 and $y_{k+1} = x_{k+1} + \beta_{k+1}(x_{k+1} - x_k)$

The quantity x_{k+1} is obtained by using an optimization method $\mathcal M$ for approximately solving:

$$x_{k+1} pprox \operatorname*{arg\,min}_{w \in \mathbb{R}^p} \left\{ f(w) + \frac{\kappa}{2} \|w - y_k\|^2 \right\},$$

Catalyst provides Nesterov's acceleration to $\mathcal M$ with...

- restart strategies for solving the sub-problems;
- global complexity analysis resulting in theoretical acceleration.
- parameter choices (as a consequence of the complexity analysis);

see also [Frostig et al., 2015] and [Paquette, Lin, Drusvyatskiy, Mairal, and Harchaoui, 2017]

Presentation borrowed from Mark Schmidt, NIPS OPT 2010

 Quasi-Newton methods work with the parameter and gradient differences between successive iterations:

$$s_k \triangleq x_{k+1} - x_k, \quad y_k \triangleq \nabla f(x_{k+1}) - \nabla f(x_k).$$

Presentation borrowed from Mark Schmidt, NIPS OPT 2010

 Quasi-Newton methods work with the parameter and gradient differences between successive iterations:

$$s_k \triangleq x_{k+1} - x_k, \quad y_k \triangleq \nabla f(x_{k+1}) - \nabla f(x_k).$$

• They start with an initial approximation $B_0 \triangleq \sigma I$, and choose B_{k+1} to interpolate the gradient difference:

$$B_{k+1}s_k=y_k.$$

Presentation borrowed from Mark Schmidt, NIPS OPT 2010

 Quasi-Newton methods work with the parameter and gradient differences between successive iterations:

$$s_k \triangleq x_{k+1} - x_k, \quad y_k \triangleq \nabla f(x_{k+1}) - \nabla f(x_k).$$

• They start with an initial approximation $B_0 \triangleq \sigma I$, and choose B_{k+1} to interpolate the gradient difference:

$$B_{k+1}s_k=y_k.$$

• Since B_{k+1} is not unique, the Broyden-Fletcher-Goldfarb-Shanno (BFGS) method chooses the symmetric matrix whose difference with B_k is minimal:

$$B_{k+1} = B_k - \frac{B_k s_k s_k B_k}{s_k B_k s_k} + \frac{y_k y_k^\top}{y_k^\top s_k}.$$

Presentation borrowed from Mark Schmidt, NIPS OPT 2010

• Update skipping/damping or a sophisticated line search (Wolfe conditions) can keep B_{k+1} positive-definite.

- Update skipping/damping or a sophisticated line search (Wolfe conditions) can keep B_{k+1} positive-definite.
- They perform updates of the form

$$x_{k+1} \leftarrow x_k - \eta_k B_k^{-1} \nabla f(x_k).$$

Presentation borrowed from Mark Schmidt, NIPS OPT 2010

- Update skipping/damping or a sophisticated line search (Wolfe conditions) can keep B_{k+1} positive-definite.
- They perform updates of the form

$$x_{k+1} \leftarrow x_k - \eta_k B_k^{-1} \nabla f(x_k).$$

• The BFGS method has a superlinear convergence rate.

- Update skipping/damping or a sophisticated line search (Wolfe conditions) can keep B_{k+1} positive-definite.
- They perform updates of the form

$$x_{k+1} \leftarrow x_k - \eta_k B_k^{-1} \nabla f(x_k).$$

- The BFGS method has a superlinear convergence rate.
- But, it still uses a dense $p \times p$ matrix B_k .

- Update skipping/damping or a sophisticated line search (Wolfe conditions) can keep B_{k+1} positive-definite.
- They perform updates of the form

$$x_{k+1} \leftarrow x_k - \eta_k B_k^{-1} \nabla f(x_k).$$

- The BFGS method has a superlinear convergence rate.
- But, it still uses a dense $p \times p$ matrix B_k .
- Instead of storing B_k , the **limited-memory BFGS** (L-BFGS) method stores the previous I differences s_k and y_k .

- Update skipping/damping or a sophisticated line search (Wolfe conditions) can keep B_{k+1} positive-definite.
- They perform updates of the form

$$x_{k+1} \leftarrow x_k - \eta_k B_k^{-1} \nabla f(x_k).$$

- The BFGS method has a superlinear convergence rate.
- But, it still uses a dense $p \times p$ matrix B_k .
- Instead of storing B_k , the **limited-memory BFGS** (L-BFGS) method stores the previous I differences s_k and y_k .
- We can solve a linear system involving these updates when B_0 is diagonal in O(dl) [Nocedal, 1980].

Limited-Memory BFGS (L-BFGS)

Remarks

- using the right initialization B_0 is crucial.
- the calibration of the line-search is also an art.

Limited-Memory BFGS (L-BFGS)

Remarks

- using the right initialization B_0 is crucial.
- the calibration of the line-search is also an art.

Pros

• a big practical success of smooth optimization.

Limited-Memory BFGS (L-BFGS)

Remarks

- using the right initialization B_0 is crucial.
- the calibration of the line-search is also an art.

Pros

• a big practical success of smooth optimization.

Cons

- worst-case convergence rates for strongly-convex functions are linear, but no better than the gradient descent method.
- proximal variants typically requires solving many times

$$\min_{x\in\mathbb{R}^d}\frac{1}{2}(x-z)B_k(z-z)+\psi(x).$$

no guarantee of approximating the Hessian.

QuickeNing

Main recipe

- L-BFGS applied to the smoothed objective F with inexact gradients [see Friedlander and Schmidt, 2012].
- inexact gradients are obtained by solving sub-problems using a first-order optimization method M;
- ideally, M is able to adapt to the problem structure (finite sum, composite regularization).
- replace L-BFGS steps by proximal point steps if no sufficient decrease is estimated ⇒ no line search on F;

Obtaining inexact gradients

Algorithm Procedure ApproxGradient

input Current point x in \mathbb{R}^d ; smoothing parameter $\kappa > 0$.

1: Compute the approximate mapping using an optimization method \mathcal{M} :

$$z pprox \operatorname*{arg\,min}_{w \in \mathbb{R}^d} \left\{ h(w) \stackrel{\triangle}{=} f(w) + \frac{\kappa}{2} \|w - x\|^2
ight\},$$

2: Estimate the gradient $\nabla F(x)$

$$g = \kappa(x - z).$$

output approximate gradient estimate g, objective value $F_a \stackrel{\triangle}{=} h(z)$, proximal mapping z.

Julien Mairal

Algorithm QuickeNing

input x_0 in \mathbb{R}^p ; number of iterations K; $\kappa > 0$; minimization algorithm \mathcal{M} .

- 1: Initialization: $(g_0, F_0, z_0) = \text{ApproxGradient}(x_0, \mathcal{M}); B_0 = \kappa I.$
- 2: **for** k = 0, ..., K 1 **do**
- 3: Perform the Quasi-Newton step

$$egin{aligned} x_{\mathsf{test}} &= x_k - B_k^{-1} g_k \ (g_{\mathsf{test}}, F_{\mathsf{test}}, z_{\mathsf{test}}) &= \mathsf{ApproxGradient}\left(x_{\mathsf{test}}, \mathcal{M}
ight) \,. \end{aligned}$$

- 4: if $F_{\text{test}} \leq F_k \frac{1}{2\kappa} ||g_k||^2$, then
- 5: $(x_{k+1}, g_{k+1}, F_{k+1}, z_{k+1}) = (x_{\text{test}}, g_{\text{test}}, F_{\text{test}}, z_{\text{test}}).$
- 6: **else**
- 7: Update the current iterate with the last proximal mapping:

$$egin{aligned} x_{k+1} &= z_k = x_k - (1/\kappa) g_k \ (g_{k+1}, F_{k+1}, z_{k+1}) &= \mathsf{ApproxGradient}\left(x_{k+1}, \mathcal{M}
ight) \,. \end{aligned}$$

- 8: **end if**
- 9: update $B_{k+1} = \text{L-BFGS}(B_k, x_{k+1} x_k, g_{k+1} g_k)$.
- 10: end for

output last proximal mapping z_K (solution).

Algorithm QuickeNing

input x_0 in \mathbb{R}^p ; number of iterations K; $\kappa > 0$; minimization algorithm \mathcal{M} .

- 1: Initialization: $(g_0, F_0, z_0) = \text{ApproxGradient}(x_0, \mathcal{M}); B_0 = \kappa I.$
- 2: **for** k = 0, ..., K 1 **do**
- 3: Perform the Quasi-Newton step

$$egin{aligned} x_{ ext{test}} &= x_k - B_k^{-1} g_k \ (g_{ ext{test}}, F_{ ext{test}}, z_{ ext{test}}) &= ext{ApproxGradient}\left(x_{ ext{test}}, \mathcal{M}
ight) \,. \end{aligned}$$

The main characters:

- the sequence $(x_k)_{k>0}$ that minimizes F;
- the sequence $(z_k)_{k\geq 0}$ produced by $\mathcal M$ that minimizes f;
- the gradient approximations $g_k \approx \nabla F(x_k)$;
- the function value approximations $F_k \approx \nabla F(x_k)$;
- an L-BFGS update with inexact gradients;
- an approximate sufficient descent condition.

10: ena tor

output last proximal mapping z_K (solution).

Requirements on ${\mathcal M}$ and restarts

Method \mathcal{M}

• Say a sub-problem consists of minimizing h; we want \mathcal{M} to produce a sequence of iterates $(w_t)_{t>0}$ with linear convergence rate

$$h(w_t) - h^* \leq C_{\mathcal{M}} (1 - \tau_{\mathcal{M}})^t (h(w_0) - h^*).$$

Restarts

• When f is smooth, we **initialize** $w_0 = x$ when solving

$$\min_{w\in\mathbb{R}^d}\left\{f(w)+\frac{\kappa}{2}\|w-x\|^2\right\}.$$

• When $f = f_0 + \psi$ is composite, we use the initialization

$$w_0 = \operatorname*{arg\,min}_{w \in \mathbb{R}^d} \left\{ f_0(x) + \langle \nabla f_0(x), w - x \rangle + \frac{L + \kappa}{2} \|w - x\|^2 + \psi(w) \right\}.$$

Julien Mairal QuickeNing 1

When do we stop the method \mathcal{M} ?

Three strategies

- (a) use a **pre-defined sequence** $(\epsilon_k)_{k\geq 0}$ and stop the optimization method \mathcal{M} when the approximate proximal mapping is ϵ_k -accurate.
- (b) define a **stopping criterion** that depends on quantities that are available at iteration *k*.
- (c) use a **pre-defined budget** $T_{\mathcal{M}}$ of iterations of the method \mathcal{M} for solving each sub-problem.

When do we stop the method \mathcal{M} ?

Three strategies

- (a) use a **pre-defined sequence** $(\epsilon_k)_{k\geq 0}$ and stop the optimization method \mathcal{M} when the approximate proximal mapping is ϵ_k -accurate.
- (b) define a **stopping criterion** that depends on quantities that are available at iteration *k*.
- (c) use a **pre-defined budget** $T_{\mathcal{M}}$ of iterations of the method \mathcal{M} for solving each sub-problem.

Remarks

- (a) is the **less practical** strategy.
- (b) is simpler to use and conservative (compatible with theory).
- (c) requires $T_{\mathcal{M}}$ to be large enough in theory. The aggressive strategy $T_{\mathcal{M}} = n$ for an incremental method is extremely simple to use and effective in practice.

When do we stop the method \mathcal{M} ?

Three strategies in details for μ -strongly convex f

(a) use a **pre-defined sequence** $(\epsilon_k)_{k\geq 0}$ and stop the optimization method \mathcal{M} when the approximate proximal mapping is ϵ_k -accurate.

$$arepsilon_k = rac{1}{2} C (1-
ho)^{k+1} \quad ext{with} \quad C \geq f(x_0) - f^* \ ext{and} \
ho = rac{\mu}{4(\mu+\kappa)}.$$

(b) For minimizing $h(w) = f(w) + (\kappa/2)||w - x||^2$, stop when

$$h(w_t) - h^{\star} \leq \frac{\kappa}{36} \|w_t - x\|^2.$$

(c) use a **pre-defined budget** $T_{\mathcal{M}}$ of iterations of the method \mathcal{M} for solving each sub-problem with

$$T_{\mathcal{M}} = \frac{1}{ au_{\mathcal{M}}} \log \left(19 C_{\mathcal{M}} \frac{L + \kappa}{\kappa} \right)$$
. (be more aggressive in practice)

Julien Mairal QuickeNing 19/30

Remarks and global complexity

Composite objectives and sparsity

Consider a composite problem with a sparse solution (e.g., $\psi = \ell_1$). The method produces two sequences $(x_k)_{k\geq 0}$ and $(z_k)_{k\geq 0}$;

- $F(x_k) \to F^*$, minimizes the **smoothed objective** \Rightarrow no sparsity;
- $f(z_k) \to f^*$, minimizes the **true objective** \Rightarrow the iterates may be sparse if \mathcal{M} handles composite optimization problems;

Global complexity

The number of iterations of $\mathcal M$ to guarantee $f(z_k)-f^\star\leq \varepsilon$ is at most

- $\tilde{O}(\frac{\mu+\kappa}{\tau_M\mu}\log(1/\varepsilon))$ for μ -strongly convex problems.
- $\tilde{O}(\frac{\kappa R^2}{\tau_{ME}})$ for convex problems.

Global Complexity and choice of κ

Example for gradient descent

With the right step-size, we have $\tau_{\mathcal{M}}=(\mu+\kappa)/(L+\kappa)$ and the complexity for $\mu>0$ becomes

$$\tilde{O}\left(\frac{L+\kappa}{\mu}\log(1/\varepsilon)\right)$$
.

Example for SVRG for minimizing the sum of n functions $\tau_{\mathcal{M}} = \min(1/n, (\mu + \kappa)/(L + \kappa))$ and the complexity for $\mu > 0$ is

$$\tilde{O}\left(\max\left(\frac{\mu+\kappa}{\mu}\textit{n},\frac{L+\kappa}{\mu}\right)\log(1/\varepsilon)\right).$$

Julien Mairal QuickeNing 21/30

Global Complexity and choice of κ

Example for gradient descent

With the right step-size, we have $\tau_{\mathcal{M}}=(\mu+\kappa)/(L+\kappa)$ and the complexity for $\mu>0$ becomes

$$\tilde{O}\left(\frac{L+\kappa}{\mu}\log(1/\varepsilon)\right)$$
.

Example for SVRG for minimizing the sum of n functions $\tau_{\mathcal{M}} = \min(1/n, (\mu + \kappa)/(L + \kappa))$ and the complexity for $\mu > 0$ is

$$\tilde{O}\left(\max\left(\frac{\mu+\kappa}{\mu}n,\frac{L+\kappa}{\mu}\right)\log(1/\varepsilon)\right).$$

QuickeNing does not provide any theoretical acceleration, but it does not degrade significantly the worst-case performance of $\mathcal M$ (unlike L-BFGS vs gradient descent).

Julien Mairal QuickeNing

Global Complexity and choice of κ

Example for gradient descent

With the right step-size, we have $\tau_{\mathcal{M}}=(\mu+\kappa)/(L+\kappa)$ and the complexity for $\mu>0$ becomes

$$\tilde{O}\left(\frac{L+\kappa}{\mu}\log(1/\varepsilon)\right)$$
.

Example for SVRG for minimizing the sum of n functions $\tau_{\mathcal{M}} = \min(1/n, (\mu + \kappa)/(L + \kappa))$ and the complexity for $\mu > 0$ is

$$\tilde{O}\left(\max\left(rac{\mu+\kappa}{\mu}n,rac{L+\kappa}{\mu}
ight)\log(1/arepsilon)
ight).$$

Then, how to choose κ ?

- (i) assume that L-BFGS steps do as well as Nesterov
- (ii) choose κ as in Catalyst.

Julien Mairal QuickeNing 21/30

Experiments: formulations

• ℓ_2 -regularized Logistic Regression:

$$\min_{\mathbf{x} \in \mathbb{R}^d} \quad \frac{1}{n} \sum_{i=1}^n \log \left(1 + \exp(-b_i \, a_i^T \mathbf{x}) \right) + \frac{\mu}{2} \|\mathbf{x}\|^2,$$

• ℓ_1 -regularized Linear Regression (LASSO):

$$\min_{x \in \mathbb{R}^d} \quad \frac{1}{2n} \sum_{i=1}^n (b_i - a_i^T x)^2 + \lambda ||x||_1,$$

• $\ell_1 - \ell_2^2$ -regularized Linear Regression (Elastic-Net):

$$\min_{x \in \mathbb{R}^d} \quad \frac{1}{2n} \sum_{i=1}^n (b_i - a_i^T x)^2 + \lambda ||x||_1 + \frac{\mu}{2} ||x||^2,$$

Experiments: Datasets

We consider four standard machine learning datasets with different characteristics in terms of size and dimension

name	covtype	alpha	real-sim	rcv1
n	581 012	250 000	72 309	781 265
d	54	500	20 958	47 152

- we simulate the ill-conditioned regime $\mu = 1/(100n)$;
- \bullet λ for the Lasso leads to about 10% non-zero coefficients.

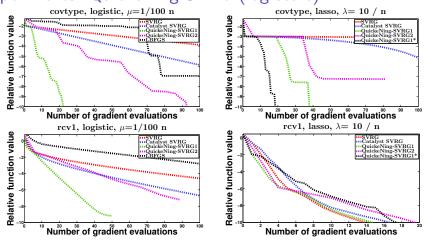

Experiments: QuickeNing-SVRG

We consider the methods

- **SVRG**: the Prox-SVRG algorithm of Xiao and Zhang [2014].
- Catalyst-SVRG: Catalyst applied to SVRG;
- L-BFGS (for smooth objectives): Mark Schmidt's implementation.
- QuickeNing-SVRG1: QuickeNing with aggressive strategy (c): one pass over the data in the inner loop.
- QuickeNing-SVRG2: strategy (b), compatible with theory.

We produce 12 figures (3 formulations, 4 datasets).

Experiments: QuickeNing-SVRG (log scale)

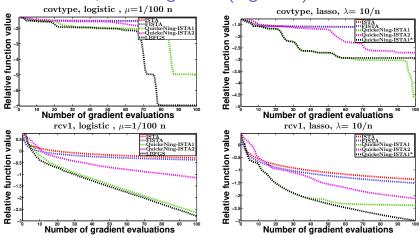

- QuickeNing-SVRG1 > SVRG, QuickeNing-SVRG2;
- QuickeNing-SVRG2 ≥ SVRG;
- QuickeNing-SVRG1 ≥ Catalyst-SVRG in 10/12 cases.

Experiments: QuickeNing-ISTA

We consider the methods

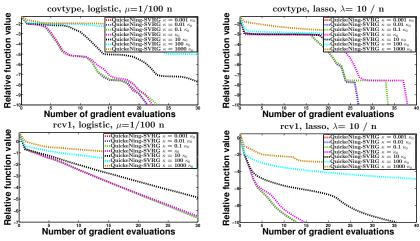

- **ISTA**: the proximal gradient descent method with line search.
- FISTA: the accelerated ISTA of Beck and Teboulle [2009].
- L-BFGS (for smooth objectives): Mark Schmidt's implementation.
- QuickeNing-ISTA1: QuickeNing with aggressive strategy (c): one pass over the data in the inner loop.
- QuickeNing-ISTA2: strategy (b), compatible with theory.

Experiments: QuickeNing-ISTA (log scale)

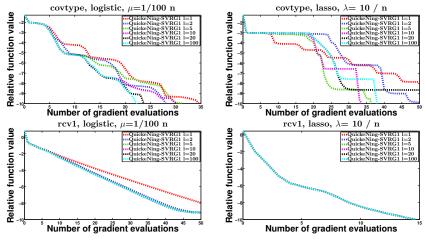

- L-BFGS (for smooth f) is slightly better than QuickeNing-ISTA1;
- QuickeNing-ISTA \geq or \gg FISTA in 11/12 cases.
- QuickeNing-ISTA1 > QuickeNing-ISTA2.

Experiments: Influence of κ

- κ_0 is the parameter (same as in Catalyst) used in all experiments;
- QuickeNing slows down when using $\kappa > \kappa_0$;
- here, for SVRG, QuickeNing is robust to small values of $\kappa!$

Experiments: Influence of I

- I = 100 in all previous experiments;
- \bullet I=5 seems to be a reasonable choice in many cases, especially for sparse problems.

Conclusions and perspectives

- QuickeNing has been a safe heuristic so far.
- It may be the first L-BFGS algorithm for composite objectives with reasonable known complexity for solving the sub-problems.
- We also have a variant for dual approaches.
- the gap between theory and practice is significant.

Perspectives

- QuickeNing-BCD, QuickeNing-SAG,SAGA,SDCA...
- Other types of smoothing techniques?

Outer-loop convergence analysis

Lemma: approximate descent property

$$F(x_{k+1}) \leq f(z_k) \leq F(x_k) - \frac{1}{4\kappa} \|\nabla F(x_k)\|_2^2 + 2\varepsilon_k.$$

Then, ε_k should be smaller than $\frac{1}{4\kappa} ||\nabla F(x_k)||_2^2$, and indeed

Outer-loop convergence analysis

Lemma: approximate descent property

$$F(x_{k+1}) \leq f(z_k) \leq F(x_k) - \frac{1}{4\kappa} \|\nabla F(x_k)\|_2^2 + 2\varepsilon_k.$$

Then, ε_k should be smaller than $\frac{1}{4\kappa} \|\nabla F(x_k)\|_2^2$, and indeed

Proposition: convergence with impractical ε_k and $\mu > 0$

If
$$\varepsilon_k \leq \frac{1}{16\kappa} \|\nabla F(x_k)\|_2^2$$
, define $\rho = \frac{\mu}{4(\mu + \kappa)}$, then

$$F(x_{k+1}) - F^* \le f(z_k) - f^* \le (1 - \rho)^{k+1} (f(x_0) - f^*).$$

Unfortunately, $\|\nabla F(x_k)\|$ is unknown.

Outer-loop convergence analysis

Lemma: approximate descent property

$$F(x_{k+1}) \leq f(z_k) \leq F(x_k) - \frac{1}{4\kappa} \|\nabla F(x_k)\|_2^2 + 2\varepsilon_k.$$

Then, ε_k should be smaller than $\frac{1}{4\kappa} \|\nabla F(x_k)\|_2^2$, and indeed

Proposition: convergence with impractical ε_k and $\mu > 0$

If
$$arepsilon_k \leq rac{1}{16\kappa} \|
abla F(x_k) \|_2^2$$
, define $ho = rac{\mu}{4(\mu + \kappa)}$, then

$$F(x_{k+1}) - F^* \le f(z_k) - f^* \le (1 - \rho)^{k+1} (f(x_0) - f^*).$$

Unfortunately, $\|\nabla F(x_k)\|$ is unknown.

Lemma: convergence with adaptive ε_k and $\mu > 0$

If
$$\varepsilon_k \leq \frac{1}{36\kappa} \|g_k\|^2$$
, then $\varepsilon_k \leq \frac{1}{16} \|\nabla F(x_k)\|^2$.

This is strategy (b). g_k is known and easy to compute.

Inner-loop complexity analysis

Restart for L-smooth functions

For minimizing h, initialize the method \mathcal{M} with $w_0 = x$. Then,

$$h(w_0) - h^* \le \frac{L + \kappa}{2\kappa^2} \|\nabla F(x)\|^2.$$
 (1)

Proof.

We have the optimality condition $\nabla f(w^*) + \kappa(w^* - x) = 0$. As a result,

$$h(w_0) - h^* = f(x) - \left(f(w^*) + \frac{\kappa}{2} \| w^* - x \|^2 \right)$$

$$\leq f(w^*) + \langle \nabla f(w^*), x - w^* \rangle + \frac{L}{2} \| x - w^* \|^2 - \left(f(w^*) + \frac{\kappa}{2} \| w^* - x \|^2 \right)$$

$$= \frac{L + \kappa}{2} \| w^* - x \|^2 = \frac{L + \kappa}{2\kappa^2} \| \nabla F(x) \|^2.$$
